Python Code for QSS Chapter 3: Measurement

Kosuke Imai, Python code by Jeff Allen

First Printing

In Chapter 2, we begin visualizing data. Python has a variety of excellent plotting libraries. This chapter uses seaborn, which is built on top of matplotlib. We occassionally leverage matplotlib to customize plots. In seaborn, we use three families of plotting functions, known as "figure-level" plots in seaborn terminology. Whenever we use one of these function families, we must specify a "kind" of plot, unless the kind we want to use is the default. The table below summarizes the families of plotting functions and the kinds of plots used in this chapter. Seaborn also has more specific, "axes-level," plotting functions, such as `histplot` and `scatterplot`. Axes-level plots are particularly useful for creating sub-plots.

Family	Kind
relplot	scatter (default), line
displot	hist (default), kde
catplot	bar, box

Section 3.1: Measuring Civilian Victimization during Wartime

[ ]:
```python
# import libraries used in chapter with conventinal aliases
import pandas as pd
import seaborn as sns
import numpy as np
import matplotlib.pyplot as plt

# import data
afghan = pd.read_csv('afghan.csv')

# summarize variables of interest
afghan['age'].describe().round(2)
```

[ ]:
```
count    2754.00
mean       32.39

```

Section 3.2: Handling Missing Data in Pandas

[ ]:
```
# print income data for first 10 respondents
afghan['income'].head(10)
```

[ ]:
```
0     2,001-10,000
1     2,001-10,000
2     2,001-10,000
3     2,001-10,000
4     2,001-10,000
5              NaN
6    10,001-20,000
7     2,001-10,000
8     2,001-10,000
9              NaN
Name: income, dtype: category
Categories (5, object): ['less than 2,000', '2,001-10,000', '10,001-20,000',
'20,001-30,000', 'over 30,000']
```

[ ]:
```
# indicate whether respondents' income is missing
afghan['income'].isnull().head(10)
```

[ ]:
```
0    False
1    False
2    False
3    False
4    False
```

```
5     True
6    False
7    False
8    False
9     True
Name: income, dtype: bool
```

[ ]:
```
# count of missing values
afghan['income'].isnull().sum()
```

[ ]:
```
154
```

[ ]:
```
# proportion of missing values
afghan['income'].isnull().mean()
```

[ ]:
```
0.05591866376180102
```

[ ]:
```
x = pd.Series([1, 2, 3, np.nan])

# pandas ignores missing values by default
x.mean()
```

[ ]:
```
2.0
```

[ ]:
```
# we can override the default behavior
x.mean(skipna=False)
```

[ ]:
```
nan
```

The pandas `crosstab` method does not have an argument for including missing values in a contingency table. Instead, we can use the `fillna` method to supply a name for the missing values.

[ ]:
```
pd.crosstab(afghan['violent.exp.ISAF'].fillna('Nonresponse'),
            afghan['violent.exp.taliban'].fillna('Nonresponse'),
            rownames=['ISAF'], colnames=['Taliban'], normalize=True)
```

[ ]:
```
Taliban           0.0       1.0  Nonresponse
ISAF
0.0          0.482934  0.128540     0.007988
1.0          0.172476  0.190995     0.007988
Nonresponse  0.002542  0.002905     0.003631
```

[ ]:
```
# listwise deletion
afghan_sub = afghan.dropna()

afghan_sub.shape[0]
```

[ ]:
```
2554
```

[ ]:
```
afghan['income'].dropna().shape[0]
```

[ ]: 2600

Section 3.3: Visualizing the Univariate Distribution

Section 3.3.1: Bar Plot

[ ]:
```
# a vector of proportions to plot
ISAF_ptable = (afghan['violent.exp.ISAF'].
               value_counts(normalize=True, dropna=False).reset_index())

ISAF_ptable
```

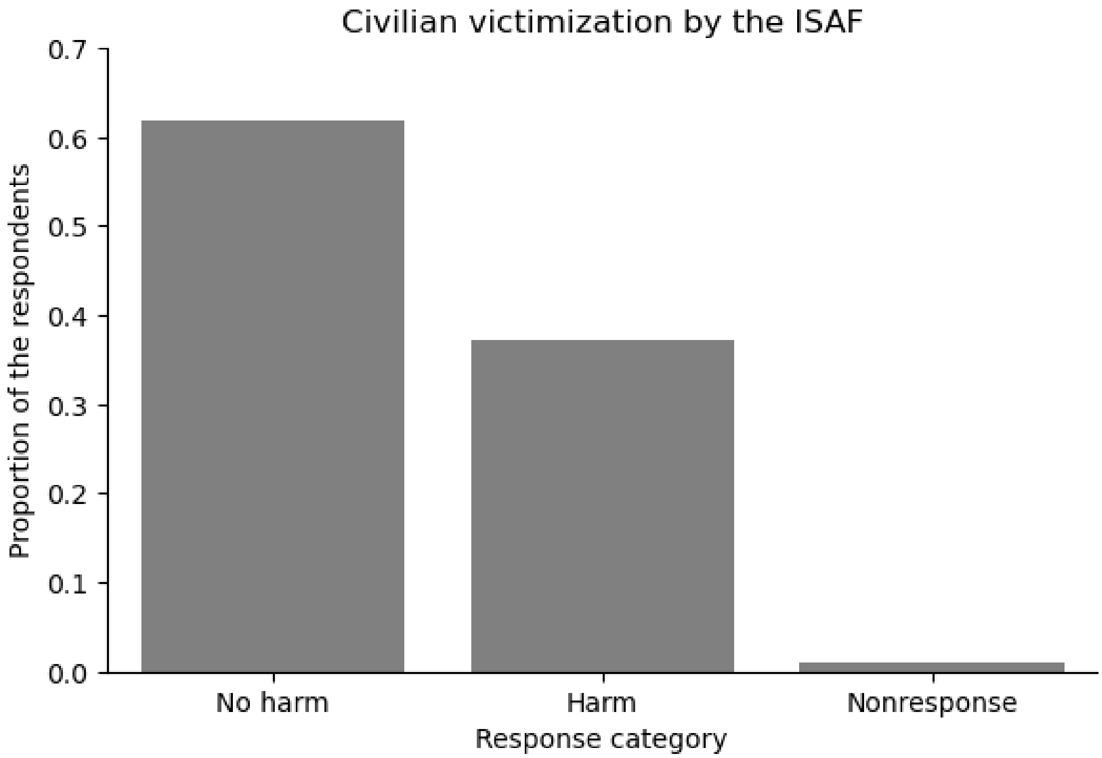
[ ]:

	violent.exp.ISAF	proportion
0	0.0	0.619463
1	1.0	0.371460
2	NaN	0.009078

[ ]:
```
# add a response column for plotting convenience
ISAF_ptable['response'] = ['No harm', 'Harm', 'Nonresponse']

# plot using the catplot family and kind='bar'
sns.catplot(
    data=ISAF_ptable, x='response', y='proportion', color='gray',
    kind='bar', estimator=sum, height=4, aspect=1.5
).set(title='Civilian victimization by the ISAF',
      xlabel='Response category', ylabel='Proportion of the respondents',
      ylim=(0, 0.7))
```

[ ]: <seaborn.axisgrid.FacetGrid at 0x2584d6f0d90>



Notice, we use `estimator=sum` because seaborn bar plots aggregate the data by a given function. The default aggregation function is `mean`. Since we have already calculated proportions, we can use `sum` to ensure there is no further aggregation. Another strategy for creating the bar plot is to use the mean aggregation directly on the original data frame categories.

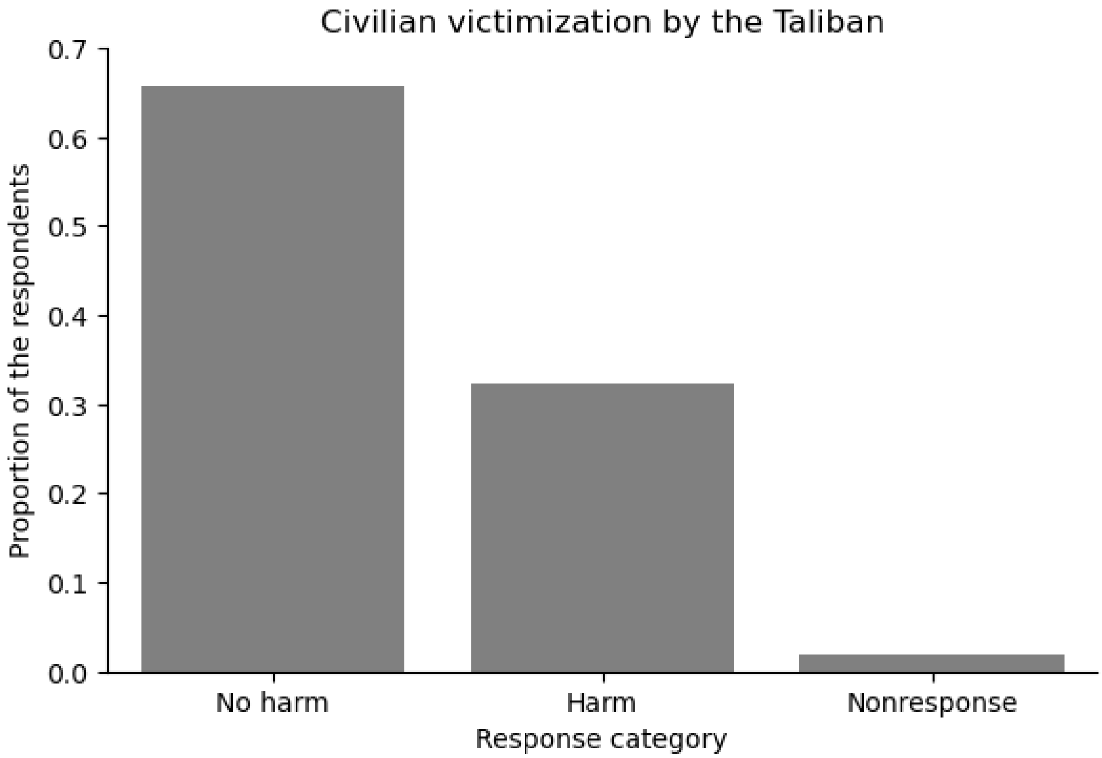
Additionally, we set the height and aspect ratios directly. The default height is 5 inches for seaborn figure-level plots, and the default aspect ratio is 1. The aspect ratio is the ratio of the width to the height. Therefore, the default width is 5 inches.

[ ]:
```
# repeat the same for the Taliban
Taliban_ptable = (afghan['violent.exp.taliban'].
                  value_counts(normalize=True, dropna=False).reset_index())

Taliban_ptable['response'] = ['No harm', 'Harm', 'Nonresponse']

sns.catplot(
    data=Taliban_ptable, x='response', y='proportion', color='gray',
    kind='bar', estimator=sum, height=4, aspect=1.5
).set(title='Civilian victimization by the Taliban',
      xlabel='Response category', ylabel='Proportion of the respondents',
      ylim=(0, 0.7))
```

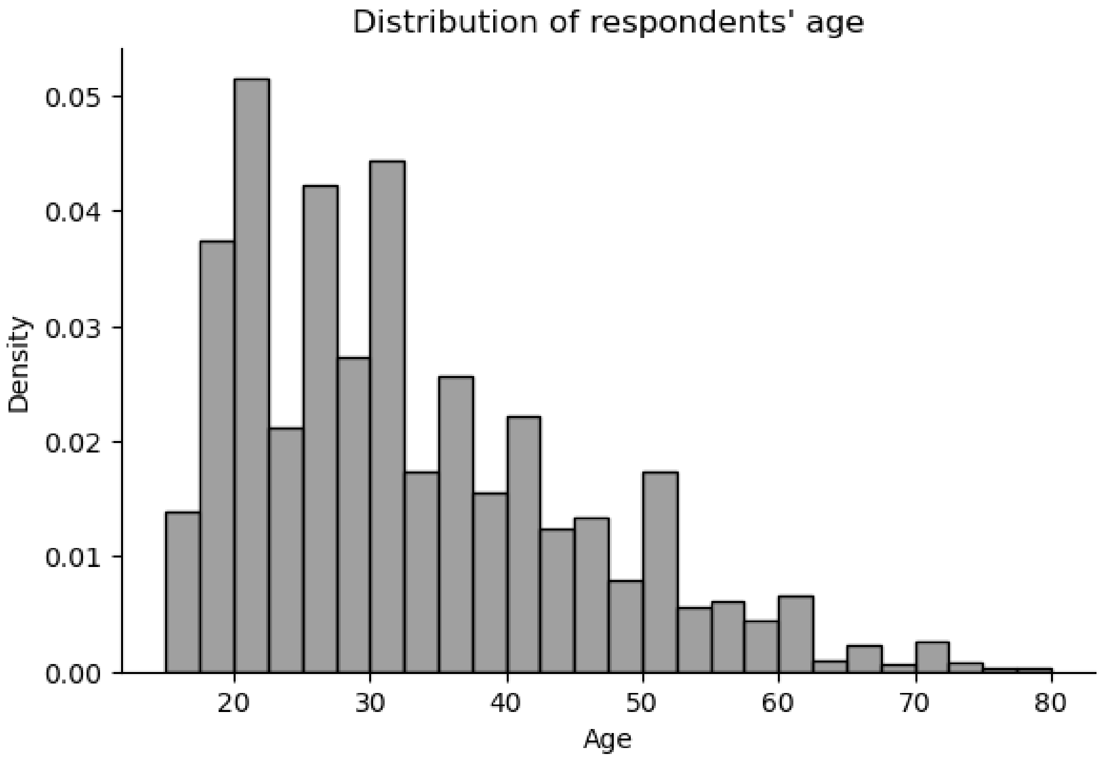
[ ]:
```
<seaborn.axisgrid.FacetGrid at 0x2584d7eafb0>
```



Section 3.3.2: Histogram

[ ]:
```
sns.displot(
    data=afghan, x='age', stat='density', color='gray',
    height=4, aspect=1.5
).set(title="Distribution of respondents' age", xlabel='Age')
```

[ ]: <seaborn.axisgrid.FacetGrid at 0x2584d7e9e70>

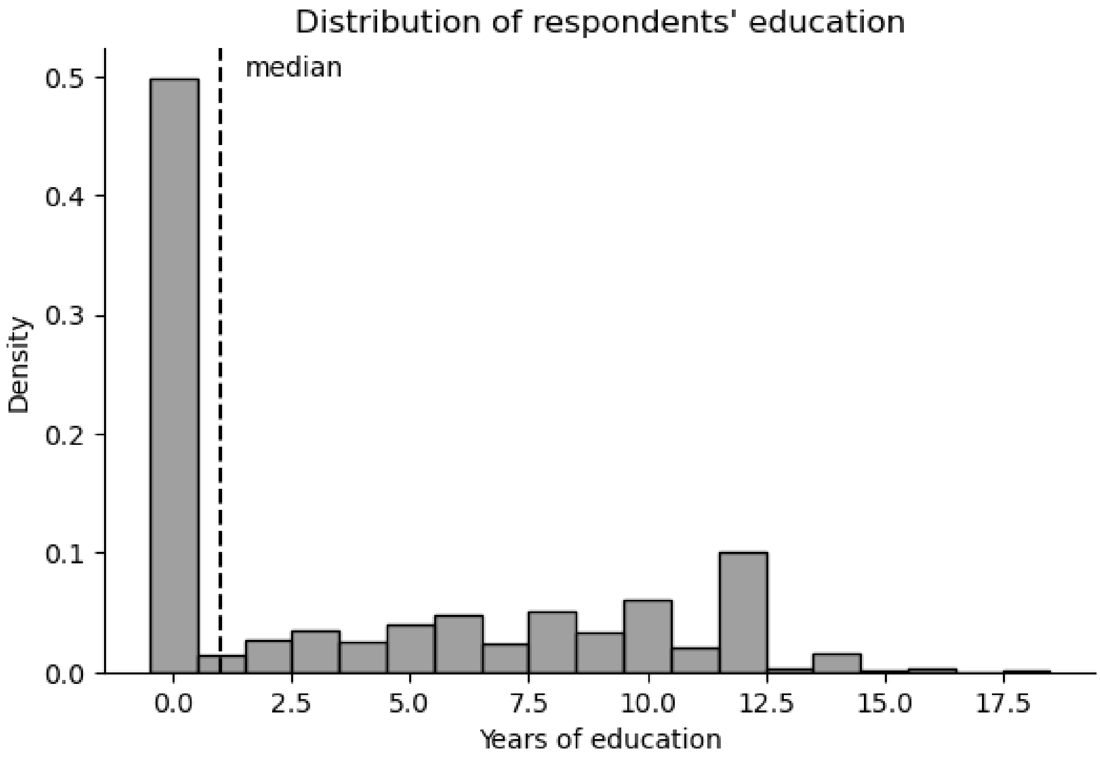


[ ]:
```
# histogram of education
# use binrange and binwidth to control the bins
sns.displot(
    data=afghan, x='educ.years', stat='density', color='gray',
    binrange=(-0.5, 18.5), binwidth=1, height=4, aspect=1.5
).set(title="Distribution of respondents' education",
      xlabel='Years of education')

# add a vertical line representing the median
plt.axvline(x=afghan['educ.years'].median(), color='black', linestyle='--')

# add a text label for the median
plt.text(x=1.5, y=0.5, s='median')
```

[ ]:
```
Text(1.5, 0.5, 'median')
```

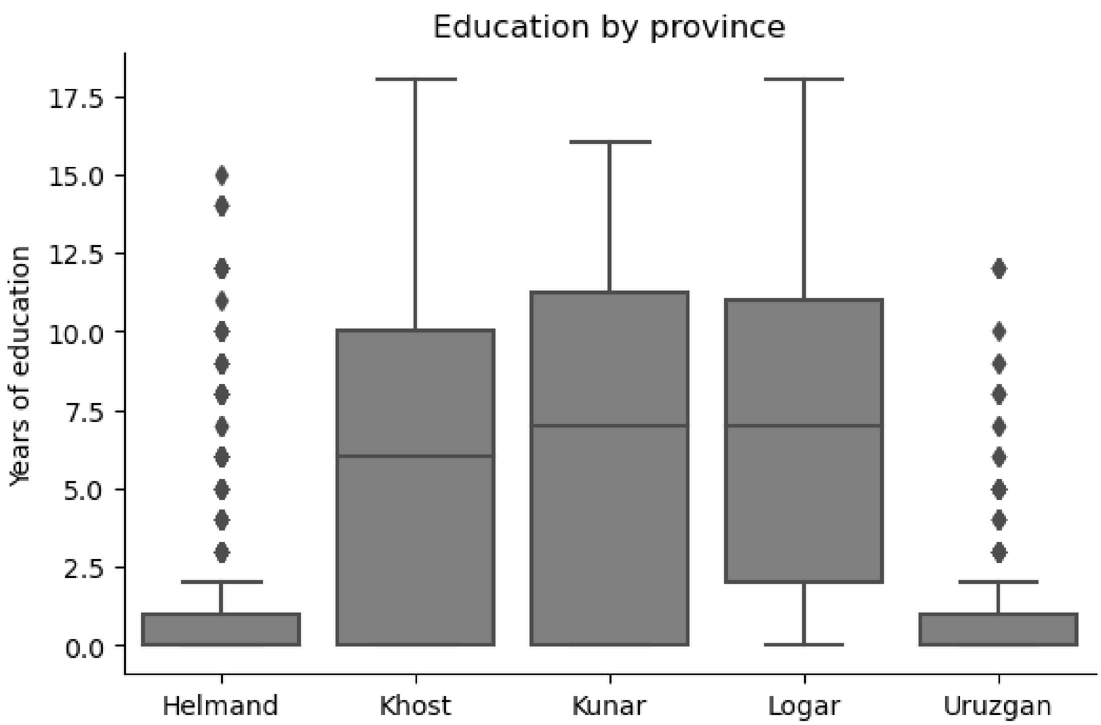


Section 3.3.3: Box Plot

[ ]:
```
# convert province to a categorical variable
# not necessary for plotting, but useful for other analyses
afghan['province'] = afghan['province'].astype('category')

sns.catplot(
    data=afghan, x='province', y='educ.years', kind='box', color='gray',
    height=4, aspect=1.5
).set(title='Education by province', xlabel='', ylabel='Years of education')
```

[ ]:
```
<seaborn.axisgrid.FacetGrid at 0x2584e06d480>
```



[ ]:
```
afghan.groupby('province')['violent.exp.taliban'].mean()
```

[ ]:
```
province
Helmand     0.504222

```

Section 3.7: Clustering

Before implementing clustering with the k-Means algorithm, we discuss numpy arrays and objects in Python, both of which are important for many Python modeling libraries.

Section 3.7.1: Numpy Arrays

Thus far, we have used the numpy library for specific tasks, such as vectorized if-else statements using `np.where()` and log transformations using `np.log()`, but we have primarily relied on pandas for our analytical infrastructure. Having at least a high-level understanding of how numpy works is important for effective data analytics in Python. Indeed, pandas is built on top of numpy. While Python modeling libraries often work well with pandas, they occasionally work better with numpy, and many modeling outputs are numpy objects, as we will see in 3.7.3.

The fundamental numpy data structure is the N-dimensional array, known as the `ndarray`. For those coming from an R background, a one-dimensional numpy array is similar to a vector in R. There are a number of ways to create a numpy vector, depending on the analytical context.

[ ]:
```
# One-dimensional arrays as vectors

# create a one-dimensional numpy array

## from a list
x = np.array([10, 20, 30, 40, 50])
```

```
x
```

[ ]: array([10, 20, 30, 40, 50])

[ ]:
```
## from a sequence
y = np.arange(10, 60, 10)

y
```

[ ]: array([10, 20, 30, 40, 50])

[ ]:
```
## from random draws from a uniform distribution between 50 and 100
z = np.random.uniform(low=50, high=100, size=10)

z
```

[ ]:
```
array([62.88569471, 83.58002802, 74.22722481, 94.58426359, 73.52605992,
       64.67316349, 91.67120295, 62.3881795 , 75.55080678, 90.9453376 ])
```

Indexing and slicing numpy arrays is similar to indexing and slicing Python lists.

[ ]:
```
# select the first observation from z
## recall, Python uses zero-based indexing
z[0]
```

[ ]: 62.885694705492696

[ ]:
```
# select the first five observations from z
## recall, Python uses "up to but not including" slicing semantics
z[0:5]
```

[ ]:
```
array([62.88569471, 83.58002802, 74.22722481, 94.58426359, 73.52605992])
```

[ ]:
```
# select the fifth observation onward
z[4:]
```

[ ]:
```
array([73.52605992, 64.67316349, 91.67120295, 62.3881795 , 75.55080678,
       90.9453376 ])
```

In base Python, we need to use for loops to perform operations on each element of a list. Numpy, by contrast, enables vectorized computations.

[ ]:
```
# conduct vectorized arithmetic: multiply each element by .25
z * .25
```

[ ]:
```
array([15.72142368, 20.895007  , 18.5568062 , 23.6460659 , 18.38151498,
       16.16829087, 22.91780074, 15.59704488, 18.8877017 , 22.7363344 ])
```

[ ]:
```
# conduct conditional vectorized arithmetic
## if an element is above 75, multiply by .25; otherwise, multiply by .75
np.where(z > 75, z * .25, z * .75)
```

[ ]:
```
array([47.16427103, 20.895007  , 55.67041861, 23.6460659 , 55.14454494,
       48.50487262, 22.91780074, 46.79113463, 18.8877017 , 22.7363344 ])
```

[ ]:
```
# calculate the sum of the elements
z.sum()
```

[ ]:
```
774.031961373088
```

[ ]:
```
# calculate the mean of the elements
z.mean()
```

[ ]:
```
77.40319613730881
```

Two-dimensional numpy arrays can be thought of as matrices.

[ ]:
```
# create a two-dimensional numpy array from a range
mat = np.arange(0, 10).reshape(5, 2)

mat
```

[ ]:
```
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
```

[ ]:
```
# select the first row
mat[0]
```

[ ]:
```
array([0, 1])
```

[ ]:
```
# select the second column
mat[:,1]
```

[ ]:
```
array([1, 3, 5, 7, 9])
```

[ ]:
```
# select the first two rows and the second column
mat[0:2, 1]
```

[ ]:
```
array([1, 3])
```

[ ]:
```
# calculate the sum of the columns
mat.sum(axis=0)
```

[ ]:
```
array([20, 25])
```

[ ]:
```
# calculate the mean of the rows
mat.mean(axis=1)
```

[ ]:
```
array([0.5, 2.5, 4.5, 6.5, 8.5])
```

[ ]:
```
# calculate the standard deviation of the columns
mat.std(axis=0)
```

[ ]:
```
array([2.82842712, 2.82842712])
```

A matrix generally must have the same data type for all elements. A data frame can have different data types for each column.

[ ]:
```
df = pd.DataFrame({'x': ['a', 'b', 'c'], 'y': [1, 2, 3]})

df.dtypes # contains a string and an integer
```

[ ]:
```
x    object
y     int64
dtype: object
```

[ ]:
```
np.array(df).dtype # produces a dtype 'O' for object; in other words, a string
```

[ ]:
```
dtype('O')
```

Section 3.7.2: Objects in Python

In Python, it is said that "everything is an object." Python makes heavy use of object oriented programming (OOP), a programming paradigm that involves grouping code and data together into objects. In OOP, an object is created from a template called a "class." The data associated with objects are generally called attributes, and the functions are called methods. Libraries like pandas, numpy, and seaborn are designed so that we do not have to worry too much about OOP particulars. Still, it is important to recognize that we are working with objects of specific classes that have attributes and methods.

[ ]:
```
# check the object class
type(congress)
```

[ ]:
```
pandas.core.frame.DataFrame
```

[ ]:
```
# review an object's methods and attributes; print the first 15
dir(congress)[0:15]
```

[ ]:
```
['T',
 '_AXIS_LEN',
 '_AXIS_ORDERS',
 '_AXIS_TO_AXIS_NUMBER',
 '_HANDLED_TYPES',
 '__abs__',
```

```
 '__add__',
 '__and__',
 '__annotations__',
 '__array__',
 '__array_priority__',
 '__array_ufunc__',
 '__bool__',
 '__class__',
 '__contains__']
```

[ ]:
```
# use a list comprehension to view the non-private attributes and methods
[item for item in dir(congress) if not item.startswith('_')][0:15]
```

[ ]:
```
['T',
 'abs',
 'add',
 'add_prefix',
 'add_suffix',
 'agg',
 'aggregate',
 'align',
 'all',
 'any',
 'apply',
 'applymap',
 'asfreq',
 'asof',
 'assign']
```

[ ]:
```
# use the data frame's value_counts "method"
congress['party'].value_counts()
```

[ ]:
```
party
Democrat      8132
Republican    6401
Other           19
Name: count, dtype: int64
```

[ ]:
```
# review the data frame's shape "attribute"
congress.shape
```

[ ]:
```
(14552, 7)
```

As we will see in 3.7.3, some important modeling libraries in Python, such as scikit-learn, rely on a more conventional OOP workflow. In such a workflow, one generally follows a few key steps:

- Select a class.
- Instantiate an object of the class and set desired parameters.
- Use the object's methods to perform operations on data.

- Extract results from the object.

Section 3.7.3: The k-Means Algorithm

[ ]:
```
from sklearn.cluster import KMeans

dwnom80 = congress.loc[congress['congress']==80, ['dwnom1', 'dwnom2']].copy()

dwnom112 = congress.loc[congress['congress']==112, ['dwnom1', 'dwnom2']].copy()

# kmeans with two clusters

## instantiate the model with parameters
k80two = KMeans(n_clusters=2, n_init=5)
k112two = KMeans(n_clusters=2, n_init=5)
```

If you are working on Windows, you may get a warning about about memory leakage associated with using KMeans on Windows. The warning will likely recommend setting the environmental variable OPM_NUM_THREADS to a certain value. To do so, follow these steps:

- (1) Click on the Windows Search button
- (2) Type "Edit the system environment variables"
- (3) Select "Environment Variables"
- (4) Click "New" under "User variables for your_username"
- (5) Enter "OMP_NUM_THREADS" for the variable name and '1' or the number recommended in the warning for the variable value
- (6) Click "OK" and close the windows

[ ]:
```
## fit the model to the data
k80two.fit(dwnom80)
k112two.fit(dwnom112)

## predict the clusters
k80two_labels = k80two.predict(dwnom80)
k112two_labels = k112two.predict(dwnom112)

type(k80two_labels) # numpy.ndarray
```

[ ]:
```
numpy.ndarray
```

[ ]:
```
# Use a list comprehension to view the non-private methods and attributes
[item for item in dir(k80two) if not item.startswith('_')]
```

[ ]:
```
['algorithm',
